Category:Standards organizations in the United States Category:Test equipment Category:Electronics industry[Role of the antigenic and functional activity of B cells in the pathogenesis of an experimental model of relapsing and progressive forms of autoimmune arthritis in rabbits]. By the use of the passive transfer of sera of rabbits with experimental arthritis (EA) into 4-day-old animals, it has been shown that the content of B-lymphocytes in the affected organs is one of the main factors that is responsible for the development of EA after primary immune response activation and for the formation of lymphoproliferative syndrome in the course of the disease. The antigens of the cells of the immune system involved in pathogenesis of EA have been identified. Analysis of the above processes have been performed by three experimental techniques: influence of the administration of the test sera on the content of B lymphocytes in the lymph nodes and synovial tissue; correlative analysis between the level of the antigenic activity of the cells of the immune system (the number of specific B cell clones), the activity of B cells (the level of Ia antigens on these cells) and the development of EA; influence of antisera on the ability of lymphocytes to produce immunoglobulins and their specificity against the antigen. The results obtained indicate that the reactive clones (monoclonal) of specific cells of the immune system play a leading role in the pathogenesis of EA. The B cells alone seem to be mainly responsible for the development f678ea9f9e
